### LUNDBYSTRAND THEATER

Chalmers University of Technology  
 Henry Feng  
 Leo Klevenås Kraft

#### EXTREME FABRICS

Making use of the technological advancements in fabrics, this theater plays its role not only in its membrane construction, but also in its room acoustics.

Shielded under a Teflon-coated fibreglass fabric, the theater is protected from Gothenburg's harsh weather, while still letting through diffused light during its summer days.

Tensile structures make very efficient long-span structures. It is cheaper, lighter and easier to construct. Because of the Teflon coating, the fabric is protected against the rain and the sun.

#### ROOF TERRACES

The space between the fabric membrane and the flat roofplate becomes an interesting area for visitors to explore. It is a roof garden with a great view eastward towards the river. Since it is covered under the membrane, it can be accessible even during the rainy days.

#### LOCATION

Located at Rungsten in the old Gothenburg Harbor, the theater becomes one of Gothenburg's many landmarks along the river. It also helps bind the city together, following Gothenburg municipality's plan to build another bridge across the river. The theater would be in a strategic location, easily accessible and a public meeting space for people living in either side of the city. What is currently an industrial area would finally become accessible for the public to experience Gothenburg's rich history as an important harbor city by being around these iconic cranes.

The Bachelor's Program in Architecture and Engineering is a collaborative study between architecture and acoustics. Each year, students participate in the International student competition organized by the Acoustical Society of America.

In this year's challenge, the object was to design a campus theater with good acoustical and conceptual properties. The project aims to prepare us for professional life through collaboration and an artistic approach to iterative design. Including several stages and a project that gradually develops.

Our project explores the potential of using textiles in acoustic applications. By being both reflective and adaptable. Making the acoustic experience adjusted to the specific needs, while also changing the visual impression with a foldable, reflective and textile roof. The design is inspired by musical instruments such as the drum. Symbolising the collaboration between sound and structure.

#### REFLECTIVE FABRIC

Using textile roof as an acoustic reflective surface is difficult to achieve. Textiles are usually lightweight and do not reflect sound in a good way. Our concept contains a material that is both heavy and flexible. We aim to achieve this by combining fibreglass and copper fiber. These materials are fairly cheap and accessible. By combining this in an interwoven pattern we suggest that we can achieve a weight of  $10 \text{ kg/m}^2$ . Using the equation  $R0=20\log(m^2/200g/m^2)+40$ , with frequencies at 125, 250, 500, 1000, 2000, 4000 Hz we receive an reduction factor of  $R0(125)=26.981$ ,  $R0(250)=34.902$ ,  $R0(500)=40.9276$ ,  $R0(1000)=46.9432$ ,  $R0(2000)=52.9588$  dB.

From these, we calculate the absorption coefficients using the relation  $R0(10) \log(R0)$  resulting in an absorption coefficient of 0.02051, 0.02013, 0.02003, 0.02000, 0.02000 which is a highly reflective material. It should be taken into consideration the actual availability of creating such a material. We have simplified the calculation by viewing the fiber as a compact material, 2 mm of fibreglass and 1 mm of copper fiber. Copper have a density of 9 g/cm<sup>3</sup> and fibreglass a density of 2.5 g/cm<sup>3</sup>. The actual flexibility and construction of the material needs to be designed and tested. Another potential error is the porosity of the material. Porosity may affect the reflectivity negatively. We have calculated the material as entirely compact which is not true in reality.

#### PERFORMANCE

For reverberation time we receive a value at 1000 Hz 0.75 s for a closed and lowered roof. This is favorable for speech where distinct sounds are wanted. For the open roof with a higher volume we receive a value of 1.5 s. More favorable for music.

For strength  $G$  we measured 0 m/sd at 1000 Hz. For closed and lowered roofs we receive a value between 8.54 dB at the front to 3.15 dB at the back. For open we receive a value of 5.19 at the front and 1.92 at the back.

For clarity  $C50$  we receive values at the front from 5.24 dB at 125 Hz to 6.44 dB at 4000 Hz. At the back we receive values at 2.28 dB at 125 Hz to 3.38 at 4000 Hz.

#### THE THEATER WALL

The shape of the theater hall is modified after the roof structure. An octagon with the scene tangent to the side. For variable acoustics we have the ability to close and open the roof. Resembling a tower in bloom, this changes the acoustic properties in the room and affects the reverberation time, making it suitable for other types of performance. It is also possible to raise and lower the textile roof, making the acoustics variable for each performance.

The actual difference the roof makes is greatly simplified and actual performance may differ to calculated values. The shape of the octagon may not be optimal for early reflections from the scene. Therefore interior walls have been constructed at the side entrance and light booths on the side of the hall, making the early reflection more prominent. The early reflection from the textile ceiling are more problematic.

The shape of the roof may not be optimal for early reflections for the current place of the scene. Although the roof is always of concave shape and should spread sound. If the source was instead placed in the center, right below the textile ceiling, the early reflection would work better, with a more clear and straight ahead reflection. This may be problematic for sound at the center being hearable at different

pieces of the hall. But then the theater hall would have different problems with the directed spread of sound.

#### WALL CONSTRUCTION

The construction of the wall elements consist of double-walled wood construction, with wood panels followed by two layers of plaster. Their wooden part. The first wall is separated at least 40 centimeters from the second wall. Lightly packed insulation is placed between them to prevent sound from coming through. The second wall is mirrored in comparison to the first. The windows are also doubled. Double sided windows are placed with a space of 40 centimeters between them, connected to the construction by springs.

#### EXTERIOR NOISE

A fairly busy and noisy harbor area makes the tactic of handling outside noise important. We have an outer tensile structure aimed to deflect outside noise. The structure is otherwise constructed of wood. With concrete to the minimum, using smart wall designs.

Interior perspective from the scene side, showing the octagon.

## REFLECTIVE FABRIC

Using textile roof as a acoustic reflective surface is difficult to achieve. Textiles are usually lightweight and do not reflect sound in a good way. Our concept contains a material that is both heavy and flexible. We aim to achieve this by combining fiberglass and copper fiber. These materials are fairly cheap and accessible. By combining this in an interwoven pattern we suggest that we can achieve a weight of  $m=14 \text{ kg/m}^2$ . Using the equation  $R_0=20\log(m)+20\log(f)-42$ . with frequencies at  $f=[125 \quad 250 \quad 500 \quad 1000 \quad 2000 \quad 4000] \text{ Hz}$  we receive an reduction factor of  $R_0=[22.8608 \quad 28.8814 \quad 34.9020 \quad 40.9226 \quad 46.9432 \quad 52.9638] \text{ dB}$

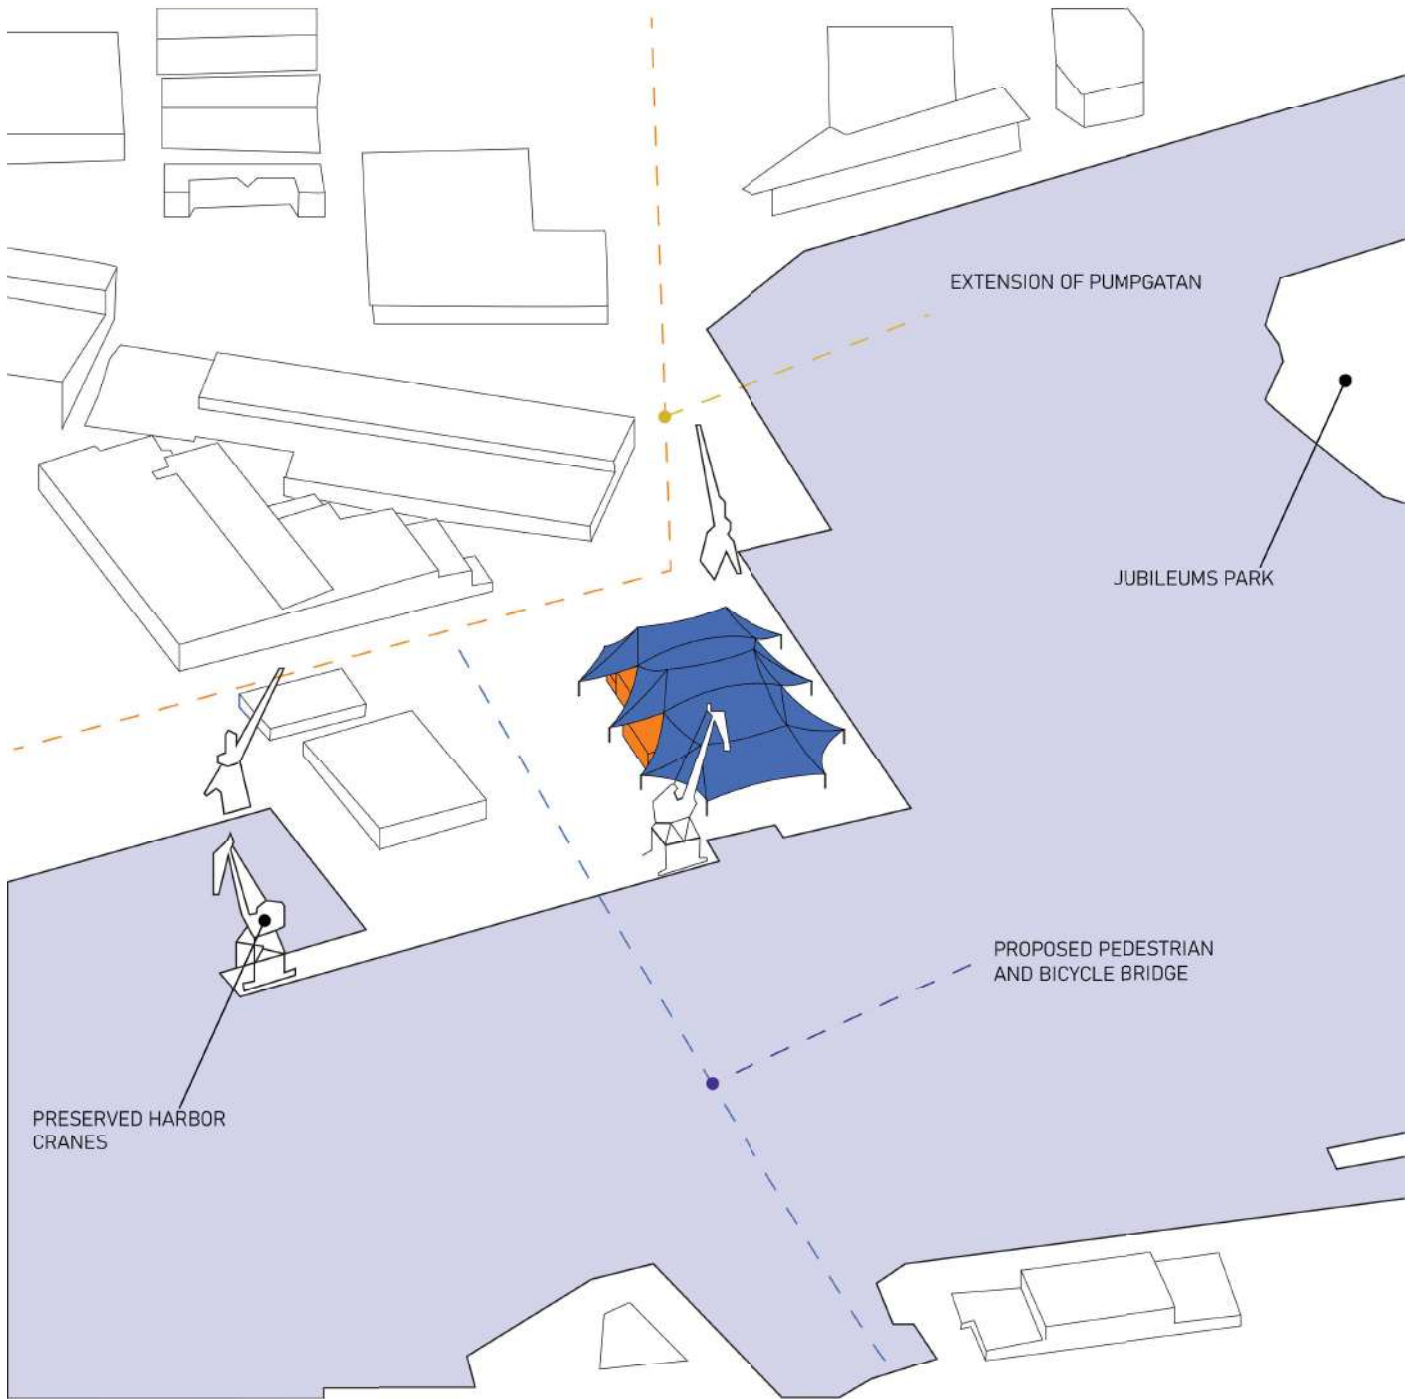

From these, we calculate the absorption coefficients using the relation

$R=10 \log 1$  Resulting in an absorption coefficient of  $\alpha=[0.0052 \quad 0.0013 \quad 0.0003 \quad 0.0001 \quad 0.0000 \quad 0.0000]$  which is a highly reflective material. It should be taken into consideration the actual achievability of creating such a material. We have simplified the calculation by viewing the fibers as a compact material. 2 mm of fiberglass and 1 mm of copper fiber. Copper have a density of  $9 \text{ gcm}^3$  and fiberglass a density of  $2.5 \text{ gcm}^3$ . The actual flexibility and construction of the material needs to be designed and tested. Another potential error is the porosity of the material. Porosity may affect the reflectivity negatively. We have calculated the material as entirely compact which is not true in reality.

## LOCATION

Located at Pumpgatan in the old Gothenburg Harbor, our theater aims to connect the city over the river. The municipality of Gothenburg has decided to construct a pedestrian bridge next to our location. Connecting the island Hisingen to the mainland. The theater would be strategically located beside busy walking traffic. At the connection from central Gothenburg to the education Hub Lindholmen. Making the theater a natural stop for commuting, eligible for survival and thriving. Also be a part of the city's landmarks bringing attention to Gothenburg's rich tradition of theater.

## THE THEATER HALL

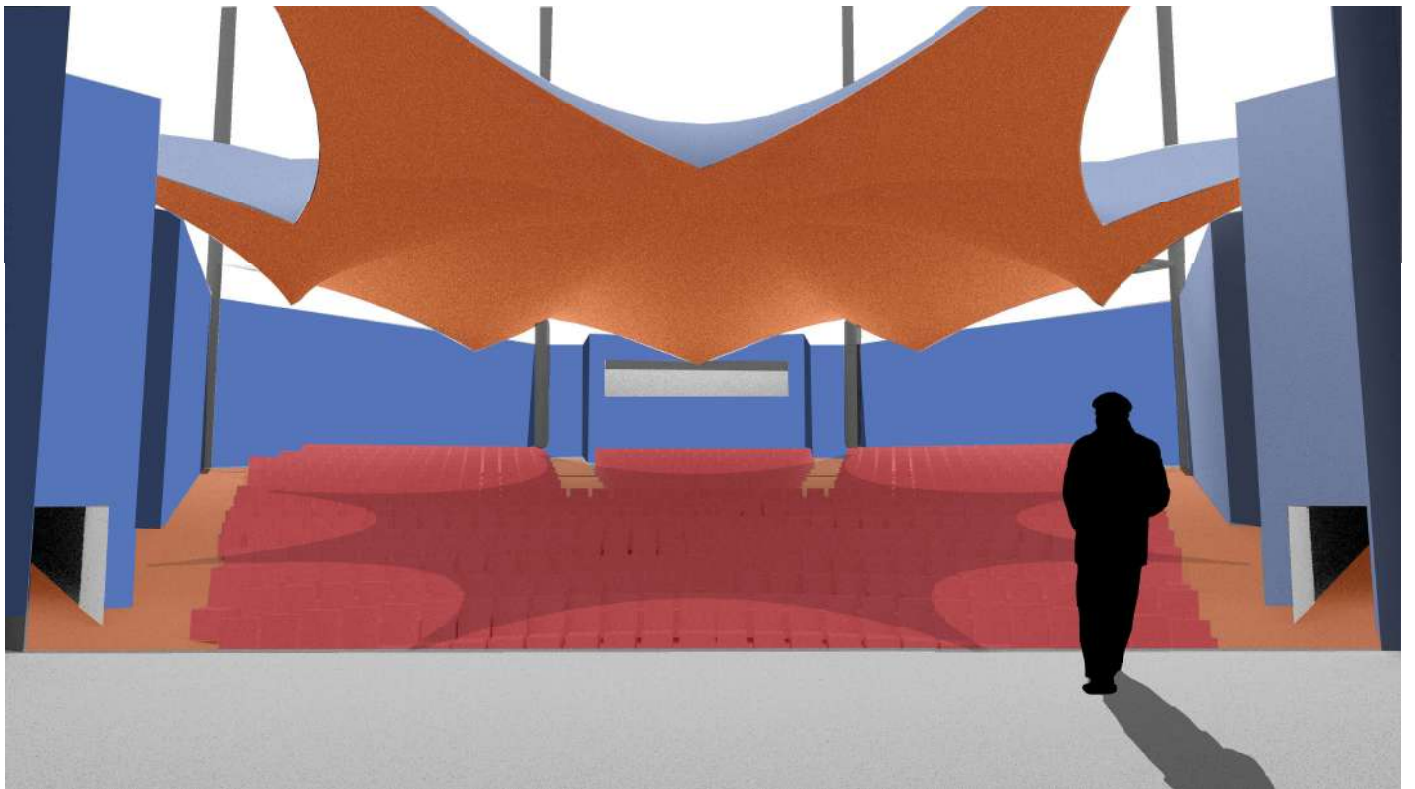

The shape of the theater hall is modelled after the roof structure. An octagon with the scene tangent to the outside. For variable acoustic we have the ability to close and open the roof. Resembling a flower in bloom This changes the acoustic properties in the roof and affects the reverberation time. Making it suitable for other types of performance. We also have the ability to heighten and lower the textile roof. Making the acoustics variable for each performance. The actual difference the roof makes is greatly simplified and actual performance may differ to calculated values. The shape of the octagon may not be optimal for early reflection from the scene. Therefore we have constructed the side entrance and light booths on the side of the hall. Making the early reflection more prominent. The early reflection from the textile roof are more problematic. The shape of the roof may not be optimal for early reflections for the current place of the scene. Although the roof is always of concave shape and should spread sound. If the source was instead placed in the center, right below the textile roof. The early reflection would work better, with a more clear and straight ahead reflection. This may be problematic for sound at the center being hearable at different places of the hall. But then the theater hall would have different problems with the directed spread of sound.

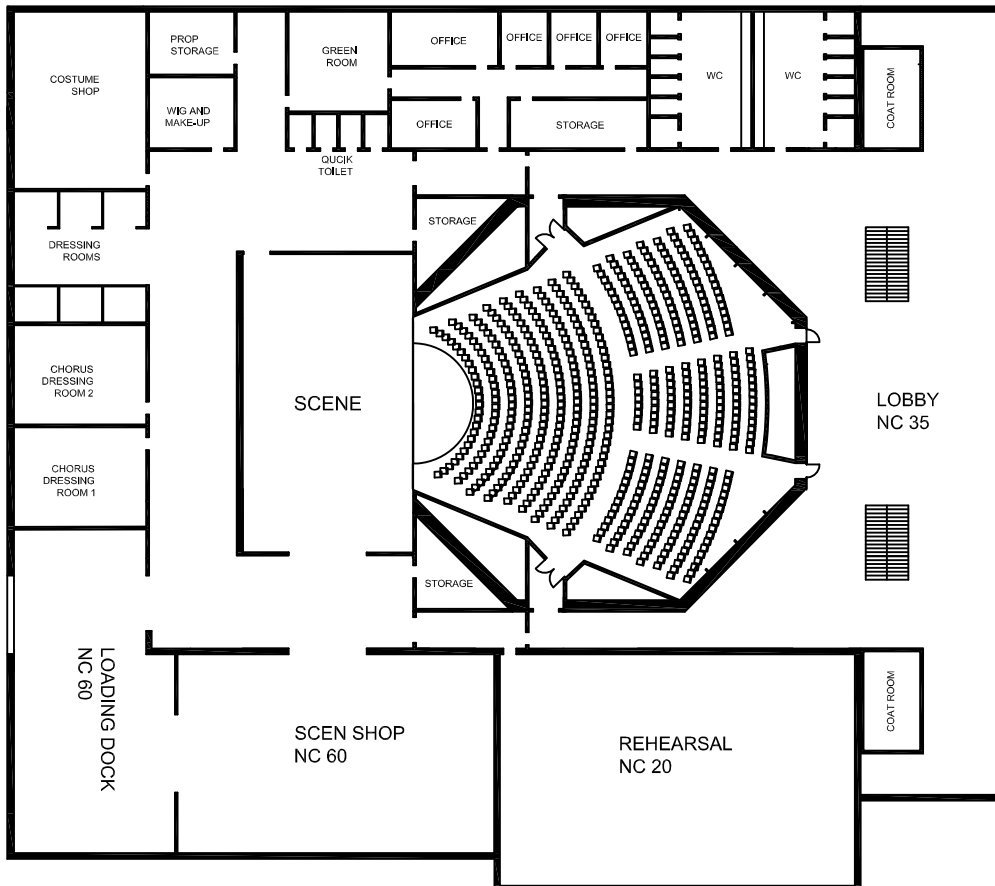

## WALL CONSTRUCTION

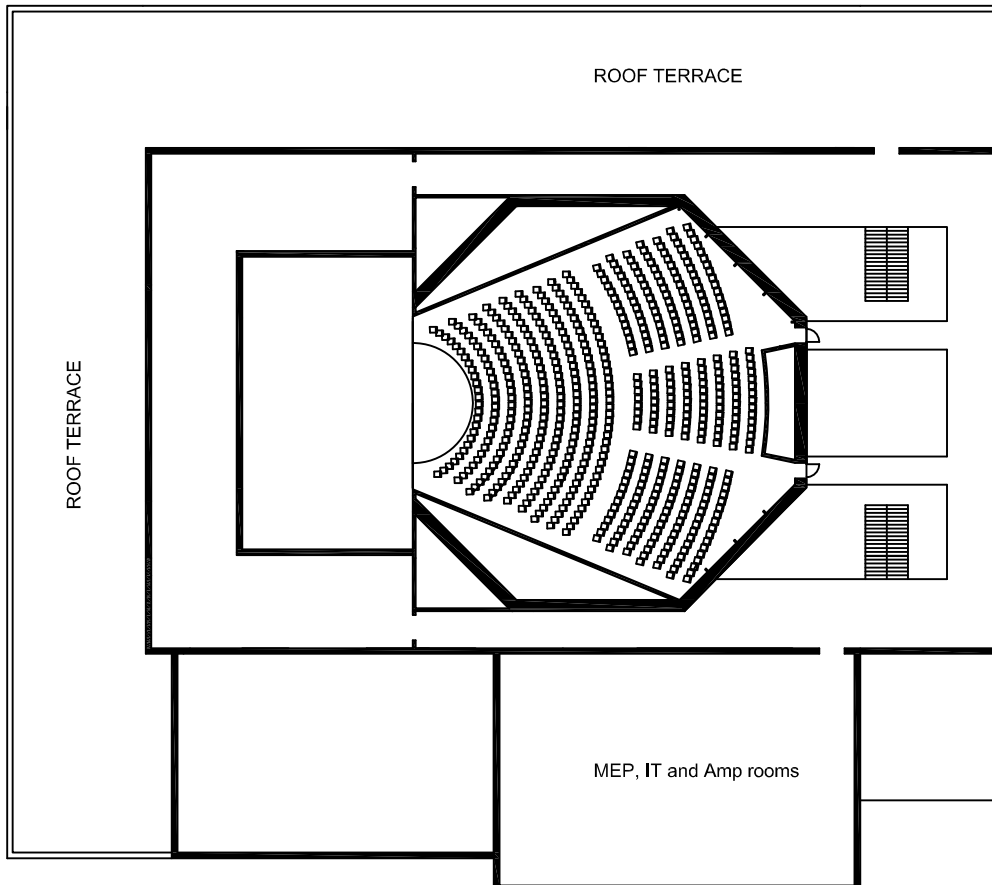

The construction of the wall elements consist of double walled wood construction. With Wood panels followed by two layers of plasters. Then wooden joist. The first wall is separated at least 40 centimeters from the second wall. Lightly packed insulation is placed between them too prevent sound from coming through. The second wall is mirrored in comparison to the first. The windows are also doubled. Double sided windows are placed with a space of 40 centimeters between them. Connected to the construction by springs.

## EXTERIOR NOISE

A fairly busy and noisy harbor area makes the tactic of handling outside noise important. We have an outer tensile structure aimed to deflect outside noise. The structure is otherwise constructed of wood. With concrete to the minimum, using smart wall designs.

## PERFORMANCE

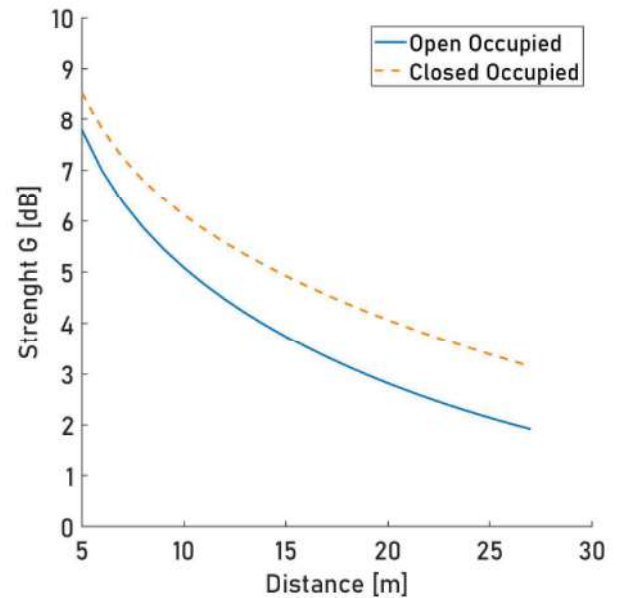

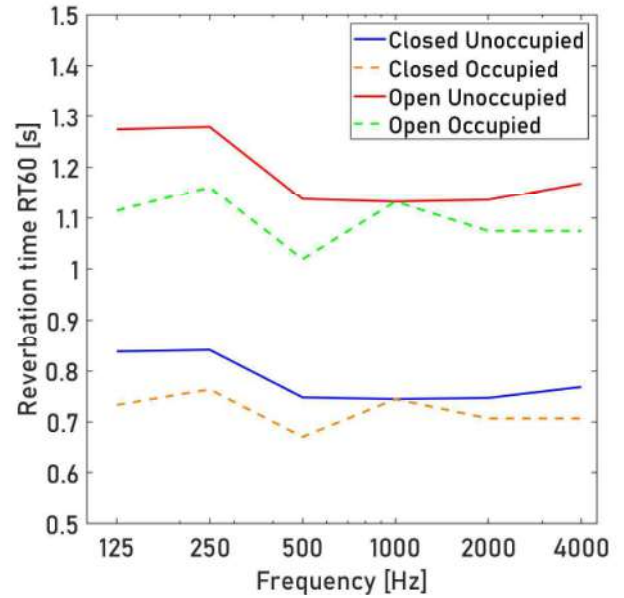

For reverberation time we receive a value at 1000 Hz 0.75 s for a closed and lowered roof. This is favorable for speech where distinct sounds are wanted. For the open roof with a higher volume we receive a value of 1.15 s. More favorable for music.

For strength G we measured Gmid at 1000 Hz. For closed and lowered roofs we receive a value between 8.54 dB at the front to 3.15 dB at the back. For open we receive a value of 7.79 at the front and 1.92 at the back.

For clarity C50 we receive values at the front from 5.34 dB at 125 Hz to 6.44 dB at 4000 Hz. At the back we receive values at 2.25 dB at 125 Hz to 3.28 at 4000 Hz.

The Helmholtz resonator reduces the reverberation time at 125 Hz by x amount.

## REFLECTION

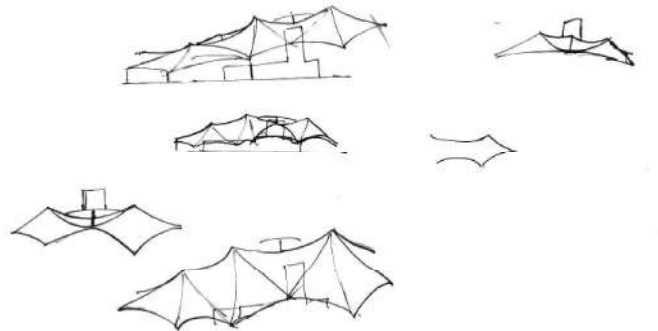

### Design Process

The process was a bumpy road with many conceptual and structural challenges. We took a bold approach in the competition by using textile. A material not typically suited for acoustics and attempted to modify its properties to meet specific needs. A clear example of this was our early idea of using textile under tension to both absorb and reflect sound. It was a concept with pure intentions, but not feasible in reality. We used drumskin leather as a metaphor for the roof structure. After discussions with acoustic professionals, the idea was discarded. However, the structure and design inspired us to develop our foldable roof, "the flower."

### Architectural Qualities

The theater is both a functional and expressive building. Connecting Gothenburg and highlighting the importance of theater. Which in itself is an architectural quality. The most notable feature is the foldable roof, which combines structural innovation with strong visual qualities. Aimed to enhance the overall experience.

### Sustainable Strategies

We initially struggled with our similarity to the circus. Looking back, this was not a bad comparison. A circus represents a humble and socially sustainable model. Able to reach remote areas and bring entertainment to everyday people. Our concept included the idea of being able to disassemble and move the entire theater. With lightweight materials like textile and wood this seemed achievable. But the lack of time made it impossible. Textile is a lightweight material that minimizes environmental effect and has many possibilities in architecture.

### Integration of Technical Disciplines

The collaboration between sound and structure was the most obvious integration. The project involved input from many fields. Indoor climate was discussed in this course. We thought about noise pollution from ventilation systems and how we would construct walls for soundproofing. Light and color were also part of the project. Taking inspiration from our field trip to the art museum. Using colors from the Gothenburg Colorist collective in our project.

## Interdisciplinary Collaboration

Collaboration was a major challenge during the course. It tested our abilities as team members. Being humble and open is essential for creating a good environment. The stress of deadlines and ambitions made collaboration difficult. Making clear intentions from the start and maintaining a respectful relation is essential for future projects.

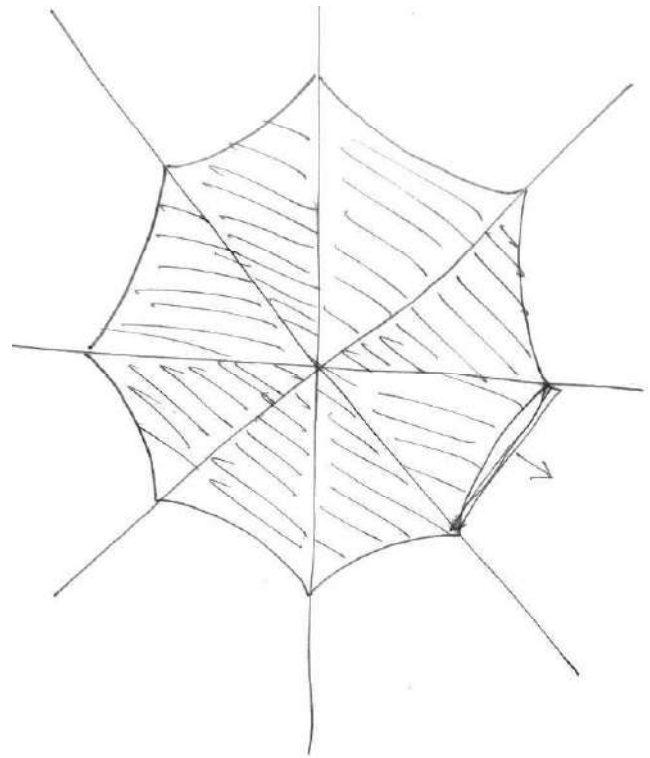

## Issues of Leadership

Leadership earlier in the process would have been helpful. In a real world scenario, with more people involved the project would feel less personal. Clearly defined roles and responsibilities would have led to a more balanced workload and an overall better project.

## Artistic Methodologies, Iterations

Parametric design played a significant role in the project. Bringing conceptual sketches with complex geometries into reality. Although we shouldn't overemphasize its importance. The true strength of the project lies in its core ideas and the conceptual foundation. Sketching and the iterative process was the most important part. Developing concepts and filtering out the good from the bad. Iteration gave us time to explore various solutions. Resulting in a more creative project.

## Afterthoughts on Three Years of Study, Future Practice

During three years of Architecture and Engineering studies I have learned many things. Among others hard work, dedication, and the competitive environment of architecture. I have developed a deeper understanding of architecture and gained confidence in my abilities. Working through difficult challenges with my classmates has brought us closer together and emphasized the importance of collaboration. Laying a solid foundation for future studies in structural engineering and a work-life with many friendly AT-colleagues.
